TURIN METER

How Turin moves: measured, calculated, analysed.

ABOUT ME

Leonardo Campese. I built Turin Meter in three weeks with AI: the questions, criteria, thresholds and checking of the numbers are my contribution; the rest was extensively engineered by the AI.

THE QUESTION

A 2020 thesis on Industry 4.0 and smart cities promised that sensors and data would change cities. Here the promise is put to the test on real data from Turin.

HOW IT WORKS

Since 3 October 2026 a Raspberry Pi reads the position of buses and trams and the traffic sensors every minute. Python scripts combine them with the census, a travel survey and open maps. Light pages, no server.

FOUR ANSWERS

6.7% About 1 arrival in 15 is more than 10 minutes late

2.1 On average, public transport takes 2.1 times as long as the car

79,598 About 1 Turin resident in 10 lives in an area with more social difficulties and few services

179 About 2 in 3 important stops lack enough spaces to leave the car

WHAT I WOULD DO

1. Priority for buses on the 10 segments where they lose the most time: ~470 minutes lost on average every weekday, between 7 and 9 a.m.
2. Park-and-ride where public transport is fast (5 of 12 entry points): there, ~80 to ~350 spaces per car park are missing.
3. Local services in the 5 zones of double disadvantage, home to ~129,000 people.

Hypotheses to check with the people who run the city: the data say where to look, not what it costs.

Three datasets that are missing: passengers per trip and stop, operating costs per line, real flows from place to place.
